Abstract A method of solving the radial Schrödinger equation for bound states is discussed. The method is based on a new piecewise representation of the second derivative operator on a set of functions that obey the boundary conditions. This representation is trivially diagonalised and leads to closed form expressions of the type $E = E(a\beta + b + c/n + ...)$ for the eigenvalues. Examples are given for power-law and logarithmic potentials.

1. INTRODUCTION

This paper discusses a method of calculating the eigenvalues of the radial Schrödinger equation (in atomic units)

$$\frac{1}{2} \frac{d^2}{dr^2} \psi + V(r)\psi = E \psi$$

subject to the boundary conditions $\psi(0) = \psi(\infty) = 0$, where $V(r)$ may include the usual centrifugal term. A brief version of this work appeared recently.

The proposed approach is based on a new piecewise representation of the differential operator $d^2/dr^2$ from eq. (1) on the set

$$U_\alpha = \{\exp(-\alpha r), r\exp(-\alpha r), r^2\exp(-\alpha r)\}$$

Using this piecewise representation for $d^2/dr^2$ in the proposed approach is equivalent to considering a continuously and infinitely...
tely piecewise approximation $\Psi(r) = \sum_k \Psi_k(r)$ to the eigenfunction $\tilde{\Psi}(r)$ of eq. (1), where in each $k$-piece the $\Psi_k(r)$ is a linear combination on the set $U_{\alpha}$ with $k \in N$:

$$
\Psi_k(r) = (A_k + B_k r + C_k r^2) \exp(-\alpha_k r) \quad \text{for} \quad r_k \leq r \leq r_{k+1}.
$$

For any $\Psi(r)$ that is a linear combination on the set $U_{\alpha}$, the unique two-point representation of the operator $d^2/dr^2$ is given by

$$
\frac{d^2}{dr^2} \Psi(r) = \frac{2\alpha^2}{\exp(1)} \Psi(r - 1/\alpha) - \alpha^2 \Psi(r)
$$

as shown in section 2. The ideal representation of the operator $d^2/dr^2$, i.e. the exact representation, would be given by its expansion on the complete set of solutions of eq. (1). This set is of course infinite and, a priori, unknown. We note that the basis set $U_{\alpha}$ is clearly a good piecewise approximation to the ideal set if the parameter $\alpha$ is larger than zero. This is due to the fact that the $U_{\alpha}$ basis satisfies the boundary condition of eq. (1) at infinity.

The representation of the second derivative operator in $U_{\alpha}$ given by eq. (3) has several unique properties. The main property is that this representation can be trivially diagonalized. Another characteristic aspect is that $U_{\alpha}$ (and hence $\Psi(r)$) depends on the free parameter $\alpha$. This variational parameter will be determined by the method itself, through the stationary condition for $E_n$. This procedure will enable us to obtain analytical expressions for the eigenvalues of eq. (1), of the form $E_n = E(\alpha n + b + c/n + \ldots)$.

This paper is organized as follows. Section 2 presents the method for a general potential $\Psi(r)$. Section 3 deals with the application of the method to power law and logarithmic potentials, together with a comparison of known results for some potentials now being studied as possible models of quark confinement ([2] and references therein). The eigenvalues are given as a function of two parameters, $a$ and $b$, in each case. The determination of these parameters in general is the subject of section 4. In section 5 the numerical accuracy
of the eigenvalues, for the same examples as in section 3, is dis- 
cussed and compared with known results. The last section contains a sum-
mary of the important features of the method.

2. THE METHOD

The method proposed here is based on the two-point piecewise represen-
tation of the second derivative operator on the set \( U_\alpha = \{ \exp(-\alpha r), r\exp(-\alpha r), r^2\exp(-\alpha r) \} \), with \( \alpha > 0 \). The main reasons for using this particular set are:

(i) Any element of \( U_\alpha \) satisfies the boundary condition in eq. (1) at infinity.
(ii) The set \( L(U_\alpha) \) of all the linear combinations of the elements of \( U_\alpha \) is closed to the operation \( d^2/dr^2 \). This means that the second derivative of any linear combination of the elements of \( U_\alpha \) is itse'lf a linear combination of the elements of \( U_\alpha \).

For a function \( \Psi \) in \( L(U_\alpha) \) the two-point representation of \( d^2/dr^2 \) can be found as the unique solution of the desired identity given by

\[
\frac{d^2}{dr^2} \Psi(r) = p \Psi(r-q) + t\Psi(r)
\]  

(4)

where \( p, q \) and \( t \) are constants. These constants are uniquely calculated by requiring that eq. (4) be valid for each of the three functions of \( U_\alpha \). The constants are

\[
p = 2 \alpha^2 e^{-1}
\]  

(5)

\[
q = 1/\alpha
\]  

(6)

\[
t = -\alpha^2
\]  

(7)

Equation (6) means that the distance between the two points must be

\[
\Delta r = 1/\alpha
\]  

(8)
This representation of $d^2/d\alpha^2$ on $U_\alpha$ is the cornerstone of this paper and is given by

$$\frac{d^2}{d\alpha^2} \psi(r) = \frac{2a^2}{e} \psi(r-1/\alpha) - a^2 \psi(r)$$

(9)

In this case, eq. (9) means that the second derivative of $Y E L (U_\alpha)$ is given exactly at any point $r$ by a linear combination of the values of $Y$ itself at the two points $r-1/\alpha$ and $r$, corresponding to property (ii) above. For a further discussion about the representation of $d^2/d\alpha^2$ on $U_\alpha$ the reader is referred to the Appendix.

Introducing a grid $r_k$ on the space coordinate $0 \leq r \leq \infty$ we may write $r_{k-1} = r_k - 1/\alpha_k$, where $r_k$ is given by

$$r_k = f(k); \quad k = 0,1,2,\ldots$$

(10)

with $f(0) > 0$ and with $r_k > r_{k-1}$ for any $k$. Note that $f$ is an order preserving function, i.e. $k > j$ implies that $f(k) > f(j)$. This grid will be determined by the method itself.

The width of each $k$-piece given by $A_{k} = |f(k) - f(k-1)|$ satisfies eq. (8), i.e. $\Delta r_k \alpha_k = 1$, and may change with $k$ since eq. (9) is a two-point formula.

From eqs. (8) and (10) it follows that

$$r_k = \frac{f(k)}{\Delta r_k \alpha_k} = \left[ \frac{f(k)}{f(k) - f(k-1)} \right] \frac{1}{\alpha_k}$$

(11)

Since $f(k) > f(k-1)$ one can readily show that (see Appendix)

$$\frac{f(k)}{f(k) - f(k-1)} = ak + b + c/k + \ldots$$

(12)

where the several $a$, $b$, $c$, etc. are constants and $k = 1,2,\ldots$.

Equation (12) shows that for any function $f(k)$ the following is true:

(i) The higher $k$-order appearing in eq. (12) is one.
As point number \( k \) increases, eq. (12) is approximately linear in \( k \).

For these reasons we may neglect the \( 0(1/k) \) contribution in eq. (12) and write

\[
\gamma_k = \frac{a_k + b}{\alpha_k}; \quad k = 1, 2, 3, \ldots
\]  

(13)

This expression will play an important role in the following discussion. One should note that, in what follows, higher-order terms could have been used in eq. (13).

Armed with eqs. (9) and (13) we now turn to the problem of calculating the \( n \)-th eigenvalue of a given potential \( V(r) \) in eq. (1). To this end we use the two-point representation of \( d^2/dr^2 \) given by eq. (9) in eq. (1) to consider the piecewise approximation

\[
\psi^{(n)}(r) = \sum_k \psi^{(n)}(r_k) \quad \text{of} \quad \tilde{\psi}^{(n)}
\]

where \( \psi^{(n)}(r) \in L(U_{\alpha_k}) \)

and \( \alpha_k \) is yet a variational parameter, obtaining

\[
-\frac{\alpha^2_k}{e} \psi^{(n)}(r_{k-1}) + \left[ \frac{1}{2} \alpha^2_k + V(r_k) \right] \psi^{(n)}(r_k) = E \psi^{(n)}(r_k)
\]

(14)

for \( k = 1, 2, \ldots \) where if \( r_0 = 0 \) then \( \psi^{(n)}(r_0) = 0 \) or if \( r_0 \neq 0 \) \( \psi^{(n)}(r_0) \) is connected to the origin by eq. (A.5) (see Appendix). Equation (14) may also be written in matrix form: \( \hat{M} \psi = \hat{E} \psi \) with \( \psi = (\psi(r_1), \psi(r_2), \psi(r_3), \ldots) \), \( \hat{M} \) and \( \hat{E} \) a bidiagonal matrix given by

\[
\begin{pmatrix}
\frac{1}{2} \alpha^2_1 + V(r_1) & 0 & 0 & 0 & \ldots \\
-\alpha^2_2/e & \frac{1}{2} \alpha^2_2 + V(r_2) & 0 & 0 & \ldots \\
0 & -\alpha^2_3/e & \frac{1}{2} \alpha^2_3 + V(r_3) & 0 & \ldots \\
\vdots & \vdots & \vdots & \ddots & \ddots \\
\end{pmatrix}
\]

(15)
with no limit imposed on its order. This matrix is the representation
of the Hamilton operator of eq. (1) and depends on the variational pa-
rameters $a, a, \ldots$ with constraints.

We now note that, owing to the bidiagonal form of $M$ the $n$-
eigenvector of $M$ has the following form:

$$\psi^{(n)}(r_k) = \begin{cases} 0 & \text{if } k < n \\ \neq 0 & \text{if } k \geq n \end{cases}$$  \hspace{1cm} (16)

and that all the eigenvalues of the eq. (14) are given trivially by
the main diagonal of $M$, with no limit imposed on its order.

Using the eigenfunction form $\psi^{(n)}(r_k)$ of eq. (16) for $k=n$
in eq. (14) and recalling eq. (13) we get

$$E_n = \frac{1}{2} \alpha_n^2 + \nu\left(\frac{am+b}{\alpha_n}\right) ; \quad n = 1, 2, \ldots$$  \hspace{1cm} (17)

where $n$ is the radial quantum number.

Since $\psi^{(n)}(r)$ is a function of the variational parameter the
variational principle for $E_n$ is $\frac{\partial E_n}{\partial \alpha} = 0$ and can be directly ap-
p lied to eq. (17) giving

$$\alpha_n + \frac{\partial}{\partial \alpha_n} \nu\left(\frac{am+b}{\alpha_n}\right) = 0$$  \hspace{1cm} (18)

The above equation also determines the parameters $\alpha$ of the ba-
sis $U_\alpha$ in any $k$-piece by means of eq. (A.8) from the Appendix and
therefore corresponds to the variational principle $\frac{\partial E}{\partial \alpha} = 0$ applied
to the whole $\psi^{(n)}(r)$.

The general procedure being proposed here to obtain the bound
states of eq. (1) begins by solving eq. (18) in order to determine
the best $\alpha_n$ as defined above. By substituting this $\alpha_n$ in eq. (17) one
obtains the eigenvalues as a known function of the constants $a$ and $b$, namely
\[ E_n = E(an + b) \]  

(19)

The determination of \( a \) and \( b \) is discussed in section 4. We shall now compare eq. (19) for the power law and logarithmic potentials with known results.

3. APPLICATION TO THE POWER-LOW AND LOGARITHMIC POTENTIALS

To further clarify the proposed method we now apply it to some well-known eigenproblems. The results obtained are compared with the exact ones, whenever possible, or to approximations. For simplicity we only analyse s-states.

For the general power law potential \( V(r) = K r^p \), with \( p > -2 \) and \( p \neq 0 \), eq. (17) gives (dropping the subscript \( n \) of \( a \))

\[ E_n = \frac{1}{2} a^2 + K(an + b)^p / \alpha^p \]  

(20)

From the stationary condition, \( \partial E_n / \partial \alpha_n = 0 \), it follows (compare with eq. (18)) that

\[ \alpha = \left[ Kp(an + b)^p \right]^{1/(p+2)} \]  

(21)

Substituting back in eq. (20), one obtains

\[ E_n = (Kp)^2/(p+2) \left( 1/2 + 1/p \right) (an + b)^2p/(p+2) \]  

(22)

as the bound state eigenvalues of the power law potential, or

\[ E_n = \alpha^2 (1/2 + 1/p) \]  

(23)

in terms of \( \alpha \) of eq. (21).

Using the same procedure for the logarithmic potential \( V(r) = K \ln(r) \), one obtains the eigenvalues

\[ E_n = \frac{K}{2} \left[ \ln(e/K) \right] + K \ln(an + b) \]  

(24)
In Table 1 we given as functions of $a$ and $b$, the solutions for some potentials which are nowadays of interest for a quark-quark confining model together with the general power law. The parameter $a$ and $b$ appearing in this table are calculated in section 4. However, as an example, the reader may recall that for $a = 1$ and $b = 0$ the Coulomb eigenvalues in Table 1 represent the correct bound-state spectrum for any order $n$.

In Table 1 two important functional relationships for the eigenvalues can be seen: with the scaling parameter $K$ and with $(an + b)$. The remaining part of this section is devoted to a comparison of these two aspects of the function $E_n = E(an + b)$ with the known results. As a source of known results we use the work of Quigg and Rosner$^2$.

The $K$ dependences of $E_n$ given in Table 1 are all correct, as can very easily be verified by rescaling the Schrödinger equation (2).

The functional dependence of the eigenvalues with the quantum number as given in Table 1 is exact for the Coulomb, linear and harmonic potentials. For the other cases no exact solutions are known. However, as can be seen from eqs. (4.33) and (4.59) from$^2$, our results indeed show the same quantum number dependence as the WKB ones. From the above comparison one sees that the proposed method reproduces the known functional dependences for the power law and logarithmic potentials with $K$ and $n$.

For other potentials, the constants $a$ and $b$ could depend on the scaling constant $K$. However, and here we emphasise this point, the functional dependence $E_n = E(an + b)$ is always the same if the function $\Psi(x)$ does not change. This can easily be verified from eqs. (17) and (18). This means that for any given potential $\Psi(x)$ a scaling of the potential may only change $a$ and $b$ but not the function $E_n = E(an + b)$.

In the next section we discuss the calculation of $a$ and $b$.

4. CALCULATIONS OF \( A \) AND \( B \)

The procedure described in the previous sections leads to closed-form expressions of the type \( E_n = E(an+b) \) for the eigenvalues.

To determine \( a \) and \( b \), we study the behaviour of the first two eigenfunctions after the outer turning-point. In order to generate accurate eigenfunctions one usually needs \( \Delta r < 1 \). In general, however, this condition would conflict with the requirement \( \Delta r = 1/\alpha \) in eq. (8). Instead of eq. (9) we therefore use the full three-point formula in \( U_\alpha \), given by eq. (A.1). The eq. (1) can be written in matrix form as \( T\Psi = E\Psi \), where now \( T \) is tridiagonal. Since we already know the functional dependence of \( a_n = \alpha(an+b) \) and \( E_n = E(an+b) \), the matrix equation \( T\Psi = E\Psi \) has only two unknowns: \( a \) and \( b \). This equation may be solved by any standard matrix technique or by using the continued fraction approach of Gerck und d'Oliveira. The latter can be conveniently run in a programmable pocket calculator.

An alternative approach is self-evident: for any two eigenvalues \( E \) and \( E_j \) calculated by some numerical method we may set up a system of two equations, for \( (a_i+b) \) and \( (a_j+b) \), to obtain \( a \) and \( b \).

In any one of the two suggested ways of determining \( a \) and \( b \) given above another advantage of the proposed method is clear: from

![Graph](image)

**Fig.1** - Behaviour of the constants \( a \) and \( b \) in \( E_n = E(an+b) \) for the power-law potential \( V(r) = K r^p \) as a function of \( p \).
the study of just two eigenfunctions or alternatively two eigenvalues the whole bound-state spectrum is obtained.

For the power law potential we show in Fig. 1 a plot of the parameters $a$ and $b$ as a functions of the power $p$. This graph is illustrative of the general range of values of $a$ and $b$.

5. NUMERICAL COMPARISON OF THE EIGENVALUES

To illustrate the accuracy of the eigenvalues calculated by the proposed method, this section presents a short numerical comparison of the bound states $E_n$ for the same potentials already discussed in section 3. The constants $a$ and $b$ were calculated using the three-point formulation from eq.(A.1) and applying to it the continued fraction approach from. The absolute error in $a$ and $b$ was chosen to be less than $10^{-5}$.

Table 2 presents the calculated values of $a$ and $b$ for some potentials. The eigenvalues $E_n$ are readily obtained from Tables 1 and 2.

The calculated eigenvalues of the Coulomb and harmonic potentials coincide with the well-known exact results for any state $n$.

For the potentials $\ln(r)$ and $r^{1/2}$ no exact solution is known. We therefore compare in Table 3 the first five calculated eigenvalues with those obtained from the WKB approximation and, when available, numerical results. It should be noted that the WKB result is not accurate for low $n$, as is well-known.

To show the effect of the constant $c$ from eq. (12) in $E_n = E(an+b+c/n)$, we calculated this expression for the linear potential. The result is

$$E_n = (3/2) \ k^{2/3} \ (1.81425n - 0.45619 + 0.01803/n)^{2/3} \ (25)$$

For comparison the result for $E(an+b)$ is

$$E_n = (3/2) \ k^{2/3} \ (1.80523n - 0.42915)^{2/3} \ (26)$$

The first column of Table 4 gives the eigenvalues as calculated from eq. (26), the second column those from eq. (25), and the last two columns the exact and WKB results respectively. The exact results correspond to the zeros of the Airy functions. As one can see the inclusion of $c/n$ improves the eigenvalues. The contribution to $E_n$ from higher order terms, i.e. $d/n^2 + \ldots$, can be inferred from the relative difference between $E(an+b+c/n)$ and $E(an+b+c/n)$. This is a general Cauchy-type criterion to estimate the intrinsic accuracy of the eigenvalues without referring to another result.

To close this section, we remark that although this paper is just intended to introduce the proposed method the eigenvalue expressions obtained in the cases of the square root and logarithmic potentials could be of interest on their own since there are no exact expressions available.

6. SUMMARY

We have presented a method to calculate the bound-states of the Schrödinger radial equation for a potential $V(r)$. The method is easy to apply and leads to an equation of the form $E_n = E(an+b + c/n + ...)$ which may be approximated by $E_n = E(an+b)$. The constants $a$ and $b$ are calculated by means of the known functions

$$\alpha_n = \alpha(an+b) \text{ and } E_n.$$  

The method is based on a new piecewise expansion of the second derivative operator in the set of functions $l e - \sim (r, \exp(-\alpha r), r^2 \exp(-\alpha r))$, with $\alpha > 0$. This set satisfies the boundary condition at infinity and has the property that any function generated by linear combinations in it can have the second derivative exactly expressed at any point $r$ as a linear combination of the values of the function itself at the points $r - Ar$, and $r + Ar$. Furthermore, for $\Delta r = 1/\alpha$ only two values of the function are needed to express exactly its second derivative at one point. This last case leads to a bidiagonal matrix that is trivially diagonalized and produced a closed-form expression for the eigenvalues. By applying the stationary condition this expression gives also the optimum value for the $a$-parameter that makes the set used the best possible piecewise approximation, within the given exponentials, to the eigenfunctions.

Another feature of the method is the sampling grid $f(k)$. The sampling grid has a non-uniform sampling distance $\Delta k$ and is determined through the constants $a$ and $b$ already mentioned.

The error of the method is determined intrinsically by the relative difference between $E(an+b)$ and $E(an+b+c/n)$, for example, for a particular state $n$. This corresponds to a Cauchy-type convergence criterion to judge when to stop the $an+b+c/n+...$ sequence. As shown, although the full result of this method is given $E_n = E(an+b+c/n+...)$ very good results are obtained by considering just $E_n = E(an+b)$.

E.G. acknowledges support from CNEN-Brazil, and J.A.C.G. from DAAD-Germany.
APPENDIX

Here we collect the following results required:

(I) representation of the operator $d^2/dr^2$ on $U_{\alpha}$,
(II) expansion of $f(k)/f(k)-f(k-1))$ in powers of $k$ and
(III) relationships for $\alpha_k$ and $r_k$.

1 - Representation of $d^2/dr^2$ on $U_{\alpha}$

The set of all possible linear combinations in $U_{\alpha}$ is defined by $L(U_{\alpha})$. Because $d^2/dr^2$ is a linear operator, the second derivative of any function of $L(U_{\alpha})$ can be expressed as a linear combination of the second derivatives of the three elements of $U_{\alpha}$.

The eigenfunctions considered in this paper are all piecewise linear combinations on the set $U_{\alpha}$ and they all belong to $L(U_{\alpha})$. The representation of the operator $d^2/dr^2$ will therefore exactly represent the second derivative of the eigenfunctions if it is exact in $U_{\alpha}$. Since $U_{\alpha}$ contains three functions, it is natural to look for a differentiation formula on $U_{\alpha}$ that may be expressed as a linear combination of three values of the function itself. Let the three values be symmetrically calculated, around the point $r$:

$$\frac{d^2}{dr^2} \psi(r) = \psi(r-\Delta r) + \nu \psi(r) + \omega \psi(r+\Delta r) \tag{A.1}$$

where $\Delta r$ has the usual meaning and $\nu$, $\nu$ and $\omega$ are constants yet to be determined.

To calculate the three constants $\nu$, $\nu$ and $\omega$ one needs three equations. These equations are simply obtained by requiring that eq. (A.1) be satisfied for each of the three functions of $U_{\alpha}$. The resulting system of equations has a unique solution given by

$$\nu = (1 + \alpha \Delta r) / [(\Delta r)^2 \exp(\alpha \Delta r)] \tag{A.2}$$

$$\nu = \alpha^2 - 2/(\Delta r)^2 \tag{A.3}$$
\[ \omega = \frac{(1-\alpha \Delta r)}{[(\Delta r)^2 \exp(-\alpha \Delta r)]} \quad (A.4) \]

For \( \alpha \Delta r = 1 \), eq. (A.4) gives \( \omega = 0 \) and eq. (A.1) coincides therefore with the two-point representation given by eq. (9).

Note that \( \alpha \) may be a complex constant, and that therefore the most general set of functions for which (A.1) is valid includes the trigonometric sine or cosine.

For later use we now calculate the representation of \( \frac{d^2}{dr^2} \) on the set \( V_\alpha = \{ \exp(-\alpha r), \ r \exp(-\alpha r) \} \) by the same procedure as above. The result is

\[ \frac{d^2 \psi}{dr^2} = \frac{2\alpha}{(\Delta r) \exp(\alpha \Delta r)} \psi'(r-\Delta r) + \frac{\alpha^2 - 2\alpha}{\Delta r} \psi(r) \quad (A.5) \]

Since this equation is a two-point formula even for \( \alpha \Delta r \neq 1 \), it can be used to connect \( \psi(n) \) to \( \psi(n)(0) = 0 \) when \( r_0 \neq 0 \) as explained in the last item of this Appendix. For \( \alpha \Delta r = 1 \) eq. (A.5) coincides with eq. (A.1).

11. Expansion of \( f(k)/(f(k)-f(k-1)) \)

Let \( f(k) \), \( k = 0,1,2,\ldots \) be a discrete sequence of numbers representing a grid on the space coordinate \( 0 \leq r < \infty \) as considered in section 2. The sequence \( f(k) \) is then given by

\[ 0 \leq f(0) < f(1) < f(2) < \ldots < \infty \]

The quotient

\[ \theta(k) = \frac{f(k)}{f(k)-f(k-1)} \quad ; \quad k = 1,2,3, \ldots \quad (A.6) \]

plays an important role in the proposed approach. First it should be noted that \( \theta(k) \) is well-defined, i.e., it has no singularities. Now, for an arbitrary integer \( M \) consider the minimal \( N \)-degree polynomial, \( N \leq M - 1 \), such that \( f(k) = P^N(k) \) for \( k = 1,2,\ldots,M \). This polynomial
exists and is unique. Note that \( f(k) - f(k-1) = \frac{P_{N-1}(k)}{Q_{N-1}(k)}, \) i.e. a polynomial of degree \( N-1 \). It then follows that

\[
\theta(k) = \frac{P^N(k)}{Q^N_2(k)} = \alpha k + b + \alpha/k + \ldots
\]

(A.7)

for \( k = 1, 2, \ldots M \) and where \( \alpha, b, \) c. etc. are constants. The above procedure may be repeated for \( M' = M + 1 \) and so on. This means that there is no imposed limit for \( M \), and eq. (12) of section 2 for \( k = 1, 2, \ldots \) is obtained.

III. Relationships for \( \alpha_k \) and \( r_k \)

From eqs. (8) and (13) it follows for \( \alpha_k \) that

\[
\alpha_{k+1} = \left[ \frac{a(k+1) + b - 1}{\alpha k + b} \right] \alpha_k ; \ k = 1, 2, \ldots
\]

and for

\[
r_{k+1} = \left[ \frac{a(k+1) + b}{a(k+1) + b - 1} \right] r_k ; \ k = 1, 2, \ldots
\]

(A.8)

(A.9)

with

\[
x_r = \begin{cases} 
\frac{a+b}{a+b-1} r_0 & \text{; with } r, \neq 0, \text{ for } a = b \neq 1 \\
\frac{a+b-1}{a+b} r_1 & \text{; with } r, = 0, \text{ for } a = b = 1
\end{cases}
\]

(A.10)

As a general condition for \( a+b \), from eqs. (A.9) and (A.10) one has

\[
a + b \geq 1
\]

(A.11)

Note also the following property: for known \( a \) and \( b \), all the \( \alpha_k \) (or \( x_k \)) are determined as soon as only one \( a \), say \( \alpha_n \) (or \( x_n \)), is determined. This means that the best \( a_n \) in the \( n \)-th piece, as given by the stationary condition \( \frac{\partial E_n}{\partial a_n} = 0 \) of eq. (18), fixes through \( a_n x_n = a_n+b \) the best \( x_n \), and therefore all the others
This is a remarkable feature of the piecewise representation used in this work.

As a final remark, from eqs. (A.10) and (14) it should be noted that if \( \alpha + \beta = 1 \) then \( r_0 = 0 \) implies that \( \psi(n)(r) = 0 \), i.e. the boundary condition at the origin of eq. (1). However, if \( \alpha + \beta \neq 1 \) the \( r_0 \neq 0 \) and \( \psi(n)(r_0) \neq 0 \). This means that one needs a connection formula between \( \psi(n)(r_0) \) and \( \psi(n)(0) = 0 \). Since \( \Delta r_0 \alpha_0 \) is free (although \( \alpha_k \Delta r_k = 1 \) for \( k \neq 0 \)) one needs a two-point representation for \( \partial^2 / \partial r^2 \) on the extra 0-th piece, with \( 0 \leq r \leq r_0 \), that is also valid for \( \alpha_0 \Delta r_0 \neq 1 \). This is accomplished with eq. (A.5).

REFERENCES

3. \( \psi(n)(r_K) = 0 \) if \( k < n \) corresponds to the \( n-1 \) zeros the oscillatory part of \( \psi(n)(r) \) and \( \psi(n)(r_K) \neq 0 \) if \( k \geq n \) corresponds to the decaying part.
5. The square-root potential has also been proposed to model the quark-quark interaction\(^6\),\(^7\).

RESUMO

Um método para a solução da equação radial de Schrödinger para estados ligados é discutido. Baseia-se em uma nova representação seccional ("piecewise") do operador derivada segunda sobre um conjunto de funções que satisfazem as condições de contorno. Essa representação é diagonalizada trivialmente e conduz a expressões fechadas do tipo \( E_n = E(\alpha n + b + \sigma/n + ...) \) para os autovalores. Potenciais que são potências e logaritmos são usados como exemplos.
